ORGANIC LIGHT EMITTING DEVICE INCLUDING LIGHT-EFFICIENCY IMPROVEMENT LAYER

CROSS-REFERENCE TO RELATED APPLICATION

Korean Patent Application No. 10-2014-0194326, filed on Dec. 30, 2014, in the Korean Intellectual Property Office, and entitled: "Organic Light Emitting Device Including Light-Efficiency Improvement Layer," is incorporated by reference herein in its entirety.

BACKGROUND

1. Field

Embodiments relate to an organic light-emitting device including a light-efficiency improvement layer.

2. Description of the Related Art

Organic light emitting devices are self-emission devices that have wide viewing angles, high contrast ratios, short response times, and excellent brightness, driving voltage, and response speed characteristics, and produce full-color images.

The organic light-emitting device may include a first electrode disposed on a substrate, and a hole transport region, an emission layer, an electron transport region, and a second electrode, which are sequentially disposed on the first electrode. Holes provided from the first electrode may move toward the emission layer through the hole transport region, and electrons provided from the second electrode may move toward the emission layer through the electron transport region. Carriers, such as holes and electrons, are recombined in the emission layer to produce excitons. These excitons change from an excited state to a ground state, thereby generating light.

A thickness of the hole transport region may be in a range of about 100 Å to about 10,000 Å, e.g., about 100 Å to about 1,000 Å. When the transport region includes a hole injection layer and a hole transport layer, the thickness of the hole injection layer may be in a range of about 100 Å to about 10,000 Å, e.g., about 100 Å to about 1,000 Å, and the thickness of the hole transport layer may be in a range of about 50 Å to about 2,000 Å, e.g., about 100 Å to about 1,500 Å. When the thicknesses of the hole transport region, the hole injection layer, and the hole transport layer are within these ranges, satisfactory hole transporting characteristics may be obtained without a substantial increase in driving voltage.

The hole transport region may further include, in addition to these materials, a charge-generation material for the improvement of conductive properties. The charge-generation material may be homogeneously or unhomogeneously dispersed in the hole transport region.

The charge-generation material may be, e.g., a p-dopant. The p-dopant may be one selected from a quinone derivative, a metal oxide, and a cyano group-containing compound. Examples of the p-dopant may include a quinone derivative, such as tetracyanoquinonedimethane (TCNQ) or 2,3,5,6-tetrafluoro-tetracyano-1,4-benzoquinonedimethane (F4-TCNQ); a metal oxide, such as a tungsten oxide or a molybdenum oxide, and Compound HT-D1 illustrated below.

<Compound HT-D1>

<F4-TCNQ>

20

The hole transport region may further include, in addition to the hole injection layer and the hole transport layer, at least one of a buffer layer and an electron blocking layer. Since the buffer layer may help compensate for an optical resonance distance according to a wavelength of light emitted from the emission layer, light-emission efficiency of a formed organic light-emitting device may be improved. For use as a material included in the buffer layer, materials that are included in the hole transport region may be used. The electron blocking layer may help prevent injection of electrons from the electron transport region.

An emission layer may be formed on the first electrode 110 or the hole transport region by using various methods, e.g., vacuum deposition, spin coating, casting, a LB method, ink-jet printing, laser-printing, or laser-induced thermal imaging. When the emission layer is formed by vacuum deposition or spin coating, deposition and coating conditions for the emission layer may be determined by referring to the deposition and coating conditions for the hole injection layer.

The emission layer may include a host and a dopant.

The host may include at least one selected from TPBi, TBADN, ADN (also referred to as "DNA"), CBP, CDBP, and TCP:

90

91

-continued

In Compounds 1 to 9, Ph indicates a phenyl group.

The phosphine oxide compound represented by Formula 1 may have a relatively high refractive index due to intermolecular interaction of a phosphine oxide group having a high dipole value. Due to the high refractive index, the phosphine oxide compound may provide high light coupling efficiency.

92

The phosphine oxide compound represented by Formula 1 may be synthesized by using a suitable organic synthetic method. A synthesis method of the phosphine oxide compound may be understood in view of the following embodiments.

Some organic light-emitting devices may have a multi-layered structure formed of various materials. Accordingly, when light that has been generated in an organic layer passes through the several layers, light may extinct in the organic light-emitting device without extraction toward the outside of the organic light-emitting device, e.g., due to total reflection. As described above, when external luminescent efficiency, e.g., efficiency of light extracted toward the outside of an organic light-emitting device is low, even when light conversion efficiency in the organic layer is high, the overall light efficiency of the organic light-emitting device may be low. However, the light-efficiency improvement layer may lead to higher efficiency of light extracted toward the outside of the organic light-emitting device based on the principle of constructive interference, when light generated in the organic layer passes through a first electrode or a second electrode toward the outside of the organic light-emitting device. Thus, the light-efficiency improvement layer may contribute to an increase in light efficiency of the organic light-emitting device.

In an implementation, as illustrated in FIG. 1, the first light-efficiency improvement layer 210 may contact, e.g., directly contact, the first electrode 110. In an implementation, as illustrated in FIG. 2, the second light-efficiency improvement layer 220 may contact, e.g., directly contact, the second electrode 190. In an implementation, as illustrated in FIG. 3, the first light-efficiency improvement layer 210 and the second light-efficiency improvement layer 220 may respectively contact, e.g., directly contact, the first electrode 110 and the second electrode 190. In an implementation, various layers may be additionally disposed between the first light-efficiency improvement layer 210 and the first electrode 110, and/or between the second light-efficiency improvement layer 220 and the second electrode 190. In an implementation, an encapsulation layer having a suitable structure may be disposed above or on an outer side of the second light-efficiency improvement layer 220 or the second electrode 190 to encapsulate the organic light-emitting device.

An organic light-emitting device according to an embodiment may be patterned corresponding to R, G, and B pixels that constitute an organic layer. Accordingly, the organic layer may include a red emission organic layer, a green emission organic layer, and a blue emission organic layer.

The light-efficiency improvement layer (including the phosphine oxide compound represented by Formula 1) may be formed as a common layer with respect to R, G, and B pixels. When the light-efficiency improvement layer is formed as a common layer with respect to R, G, and B pixels, a thickness of the light-efficiency improvement layer may be in a range of about 500 Å to about 800 Å, e.g., about 600 Å to about 700 Å. When the thickness of the light-efficiency improvement layer is within these ranges, excellent light efficiency improvement effects may be obtained.

In an implementation, the light-efficiency improvement layer may include, e.g., at least one selected from a light-efficiency improvement layer-R, a light-efficiency improvement layer-G, and a light-efficiency improvement layer-B. For example, the light-efficiency improvement layer may be patterned to correspond to R, G, and B pixels.

The term "light-efficiency improvement layer-B" used herein refers to a light-efficiency improvement layer formed on a region of an organic light-emitting device corresponding to a blue (B) pixel.

Thicknesses of the light-efficiency improvement layer-R, the light-efficiency improvement layer-G, and the light-efficiency improvement layer-B may be identical or different.

Synthesis Example 1: Synthesis of Compound 1

Compound A-1 (2.5 g, 10 mmol) and 1,4-dibromobenzene (5 g, 21 mmol) were dissolved in THF of 50 mL, and then, 230 mg of tetrakis(triphenylphosphine)palladium and an aqueous potassium carbonate solution (1.4 g, 100 mmol) were sequentially added thereto, and then, the temperature was raised to 75° C., and the result was stirred for 12 hours. The result was washed with 50 mL of ethyl acetate, and an organic layer was extracted therefrom. The organic layer was dried by using an anhydrous magnesium sulfate, and then, a solvent was removed therefrom by distillation to obtain a dry result. The result was purified by silica gel column chromatography, and then dried to remove a solvent therefrom to obtain Compound 1-1.

Synthesis of Compound 1

Intermediate 1-1 (3.6 g, 10 mmol) was dissolved in 50 mL of THF, and cooled to -78° C. n-BuLi (2.5 M, 4.8 mL) was slowly added dropwise thereto, and the resultant solution was stirred for 1 hour. The temperature was raised to -50° C., and 2.2 g of diphenylphosphine chloride was added thereto, and stirred for 10 hours. The reaction was quenched by adding 20 mL of methanol thereto, and a solvent was removed therefrom by evaporation, and the residual was dissolved in dichloromethane, and 10 mL of hydrogen peroxide (30%) was added thereto, and then stirred for 24 hours. The reaction mixture was washed twice by using 50 mL of salt water and 50 mL of pure water, and an organic layer was dried by evaporation. The result was purified by silica gel column chromatography, and a solvent was removed therefrom by drying to obtain Compound 1. An obtained compound was confirmed by ¹H NMR and MS/FAB.

NMR: (300 MHz, CDCl_3) δ (ppm) 8.8-8.5 (5H), 8.4-7.9 (9H), 7.7-7.3 (16H), m/z ; 555.18

Example 1

Compound 1 was vacuum deposited on a substrate to form a light-efficiency improvement layer having a thickness of 600 Å. A 15 Ω/cm^2 (500 Å) ITO glass substrate (a product of Corning Co., Ltd.) was formed as an anode on the light-efficiency improvement layer. 2-TNATA (a product of DUKSAN Hi-METAL Co., Ltd.) was vacuum-deposited on the anode to form a hole injection layer having a thickness of 600 Å, and 4,4'-bis[N-(1-naphthyl)-N-phenylamino]biphenyl (NPB) (a product of DUKSAN Hi-METAL Co., Ltd.) was vacuum-deposited on the hole injection layer to form a hole transport layer having a thickness of 300 Å to form a hole transport region.

CBP acting as a host and $\text{Ir}(\text{ppy})_3$ acting as a dopant were co-deposited on the hole transport region at a weight ratio of 90:10 to form an emission layer having a thickness of 400 Å.

Alq_3 was vacuum deposited on the emission layer to form an electron transport layer having a thickness of 300 Å, thereby completing the manufacture of an electron transport region.

Al was vacuum-deposited on the electron transport region to form a cathode having a thickness of 2,000 Å, thereby completing the manufacture of an organic light-emitting device.

Evaluation Example 1

External luminescent efficiency of the organic light-emitting devices of Examples 1 to 9 and Comparative Example 1 were evaluated by using PR650 Spectroscan Source Measurement Unit. (a product of PhotoResearch Company). Results thereof are shown in Table 1 below.

TABLE 1

Light-efficiency improvement layer		Efficiency (cd/A)
Example 1	Compound 1	36
Example 2	Compound 2	38
Example 3	Compound 3	36
Example 4	Compound 4	36
Example 5	Compound 5	36
Example 6	Compound 6	36
Example 7	Compound 7	36
Example 8	Compound 8	36
Example 9	Compound 9	36
Comparative Example 1	Alq3	31

Referring to Table 1, it may be seen that the organic light-emitting devices manufactured according to Examples 1 to 9 have higher external luminescent efficiency than the organic light-emitting device manufactured according to Comparative Example 1.

By way of summation and review, light efficiency of an organic light-emitting device may be classified as an internal luminescent efficiency or an external luminescent efficiency. The internal luminescent efficiency may be associated with how efficiently excitons are generated and light conversion occurs in the organic layer between a first electrode and a second electrode, (e.g., between an anode and a cathode), wherein the organic layer includes a hole transport layer, an emission layer, and an electron transport layer. The external luminescent efficiency (also called "light coupling efficiency") indicates how efficiently light generated in an organic layer is extracted or emitted toward the outside of an organic light-emitting device. Although light conversion efficiency may be high in an organic layer (e.g., even when internal luminescent efficiency is high), as long as external luminescent efficiency is low, the overall light efficiency of the organic light-emitting device may be low.

An organic light-emitting device according to an embodiment may have improved light-efficiency.

Example embodiments have been disclosed herein, and although specific terms are employed, they are used and are to be interpreted in a generic and descriptive sense only and not for purpose of limitation. In some instances, as would be apparent to one of ordinary skill in the art as of the filing of the present application, features, characteristics, and/or elements described in connection with a particular embodiment

109
